In this anatomy course, part of the Anatomy Specialization, you will learn how the components of the integumentary system help protect our body (epidermis, dermis, hair, nails, and glands), and how the musculoskeletal system (bones, joints, and skeletal muscles) protects and allows the body to move.

- The skeleton supports the body, protects internal organs, provides for movement, stores internal reserves, and provides a site for blood cell formation.
- The human body would collapse without its skeleton. Bones protect the internal organs of the body.

Without bones you would be a lump of fleshy organs. Without cartilage you would have no nose, no fingernails, and folding your arm or straightening your leg would be extremely painful. Cartilage and bone are examples of connective tissue that are widespread and very important in our bodies. Cartilage requires no blood supply and actually repels blood vessels. This, plus its rubbery and slippery qualities, makes cartilage well-suited for joints. Bone serves many important functions such as to support our body, protect delicate organs, make blood cells, and maintain critical calcium levels. Under the microscope, bone is one of the body's most beautifully constructed

organs. The exquisite design of osteons makes compact bone, pound for pound, as strong as cast iron. Most amazing is the fact that the bones of the adult skeleton are highly dynamic structures that constantly change shape to best meet the loads that are placed on them. Part 1: 39 mins. "The study of anatomy has long been essential training for painters and sculptors who want to accurately portray the human form. With hundreds of drawings and meticulously researched text, this book includes: an overview of the history of artistic anatomy; an introduction to the "language of anatomy" that makes the meaning of anatomical terms transparent, accessible, and memorable; entries on all major muscles and muscle groups, depicting each muscle's form, its interactions with the skeletal system, and its role in creating movement;

This is the second edition of this proceedings. Contributors include leading names in the field of research, addressing multiple topics, which were covered at the last Osteoimmunology conference.

The aim of this treatise is to summarize the current understanding of the mechanisms for blood flow control to skeletal muscle under resting conditions, how perfusion is elevated (exercise hyperemia) to meet the

increased demand for oxygen and other substrates during exercise, mechanisms underlying the beneficial effects of regular physical activity on cardiovascular health, the regulation of transcapillary fluid filtration and protein flux across the microvascular exchange vessels, and the role of changes in the skeletal muscle circulation in pathologic states. Skeletal muscle is unique among organs in that its blood flow can change over a remarkably large range. Compared to blood flow at rest, muscle blood flow can increase by more than 20-fold on average during intense exercise, while perfusion of certain individual white muscles or portions of those muscles can increase by as much as 80-fold. This is compared to maximal increases of 4- to 6-fold in the coronary circulation during exercise. These increases in muscle perfusion are required to meet the enormous demands for oxygen and nutrients by the active muscles. Because of its large mass and the fact

that skeletal muscles receive 25% of the cardiac output at rest, sympathetically mediated vasoconstriction in vessels supplying this tissue allows central hemodynamic variables (e.g., blood pressure) to be spared during stresses such as hypovolemic shock. Sympathetic vasoconstriction in skeletal muscle in such pathologic conditions also effectively shunts blood flow away from muscles to tissues that are more sensitive to reductions in their blood supply that might otherwise occur. Again, because of its large mass and percentage of cardiac output directed to skeletal muscle, alterations in blood vessel structure and function with chronic disease (e.g., hypertension) contribute significantly to the pathology of such disorders. Alterations in skeletal muscle vascular resistance and/or in the exchange properties of this vascular bed also modify transcapillary fluid filtration and solute movement across the microvascular barrier to influence muscle

Finally, it is clear that exercise training induces an adaptive transformation to a protected phenotype in the vasculature supplying skeletal muscle and other tissues to promote overall cardiovascular health. microarchitecture. Menopause is a condition which can increase the remodeling process in favor of resorption. Moreover, there are also some diseases, i.e. chronic kidney bone disease, that increase the possibility of fractures and the subsequent disability leading to increased mortality. However, it is clear that drugs are an essential element of the therapy and this issue is analyzed extensively in this book. Some novel pathophysiological mechanisms are also presented, offering advanced knowledge to the reader. The book includes chapters from scientific departments and researchers from all over the world.
